The study provides information for a better understanding of the development of self-regulation of eating behavior. This understanding can be important in reducing the risk of obesity and related health problems. The findings also highlight the importance of parental involvement in the development of self-regulation of eating behavior.

Table 1: Differences in the perception of food energy and energy density did not change significantly between the two groups. The group that underwent the educational intervention showed a decrease in the perception of food energy and energy density compared to the control group. This suggests that the educational intervention may have had a positive impact on the perception of food energy and energy density.
